OBJETIVE

The objective of this lab is to monitor application layer protocols, analyze their behavior, and understand their role in network communication. Additionally, it aims to review the structured cabling standard and its practical applications in network installations. Finally, the lab includes hands-on practice in performing cable punching with RJ-45 connectors and patch panels to ensure proper connectivity and compliance with industry standards.

MATERIALS & TOOLS

Some of the following materials are found in the networking laboratory and are provided by the university, others are brought by students for manual practice on cables.

- Laboratory computers with internet access
- Patch panel & face plate.
- Punch tools.
- Cable strippers & wire cutter.
- 4 to 6 meters of UTP/FTP CAT5 or CAT6.
- RJ-45 connectors.
- Cable tester.

INTRODUCTION

Modern Modern IT infrastructures depend on both physical and application layer technologies to ensure reliable connectivity, efficient communication, and secure data transmission. Organizations integrate wired and wireless networks to connect user devices, physical and virtualized servers, and cloud-based services through structured cabling and network protocols. Proper implementation of these elements is essential for maintaining a stable and scalable network.

In this lab, we will focus on two key aspects of networking: monitoring application layer protocols and understanding structured cabling. We will analyze network traffic using tools such as Wireshark, configure essential services like DNS, HTTP, and FTP, and examine how different application layer protocols interact with the transport layer. Additionally, we will apply structured cabling techniques, including cable crimping, patch panel setup, and connectivity testing to ensure proper network performance.

By combining theoretical concepts with hands-on experience, we aim to develop a deeper understanding of network infrastructure and management. This lab will not only reinforce our knowledge of application and physical layer interactions but also provide practical skills necessary for real-world networking environments.

THEORETICAL FRAMEWORK

The Application Layer is the topmost layer of the OSI model and is responsible for providing network services directly to end users. It includes protocols such as DNS, which translates domain names into IP addresses; HTTP, which enables web browsing; FTP, used for file transfers; and email protocols like SMTP and POP3, which handle email transmission and retrieval. In this lab, we will configure and analyze these protocols to understand their role in communication. The Transport Layer, while not the main focus, is essential for ensuring data reaches its destination reliably. It manages communication through ports, which identify specific services on a device. Protocols like TCP and UDP operate at this layer, with TCP ensuring reliable delivery and UDP providing faster but less reliable transmission. During the lab, we will observe how different ports correspond to

application layer services. The Physical Layer deals with the hardware components of networking, including cables, connectors, and network devices. A key part of this lab is structured cabling, which follows standards like TIA/EIA-568 to ensure organized and scalable network installations.

In this lab, we will work with UTP cables, specifically CAT5 or CAT6, which are widely used for Ethernet networking. These cables consist of four twisted pairs of copper wires that reduce electromagnetic interference and crosstalk. CAT5, commonly used for Fast Ethernet. CAT5e, improves on CAT5, supporting Gigabit Ethernet with reduced crosstalk and improved transmission quality. CAT6 is designed for Gigabit Ethernet, with better shielding against interference. CAT6a, further enhances CAT6, making it ideal for high-speed networking and data centers. Each category uses RJ-45 connectors, and in this lab, we will perform cable crimping to create functional Ethernet cables. Additionally, we will configure and test a patch panel, which helps in managing cable connections in network infrastructure, ensuring proper organization, scalability, and troubleshooting efficiency.

To analyze network traffic, we will use Wireshark, a packet capture tool that allows us to inspect how data flows through the network. This tool captures packets at different layers of the OSI model, enabling us to observe protocol behavior, identify active application layer protocols, and troubleshoot communication issues. Wireshark is crucial for network diagnostics and security analysis, as it helps detect latency issues, misconfigurations, and potential attacks by analyzing real-time traffic patterns.

To complement this lab, we will use Cisco Packet Tracer, a network simulation tool that allows us to visualize, configure, and troubleshoot network topologies. This tool provides a controlled environment where devices such as routers, switches, servers, and workstations can be configured and tested. In this lab, Packet Tracer will allow us to configure a network with various devices, simulate the behavior of application layer protocols, analyze message flow, and use simulation mode to step through packet transmission. This will help us understand protocol interactions and troubleshoot potential issues before deploying configurations in real networks, making it an essential tool for network design and learning.

EXPERIMENTS

For this section, we will use software specialized in simulating network behavior, in this case Packet Tracer. In it, we will analyze the information obtained from the protocols and packets of the application and transport layers. In this way, we will be able to understand how these network tools really work, and we will be able to move on to a real environment.

CISCO PACKET TRACER

In this first part, we will copy the given diagram and configure the different elements that we put in the Packet Tracer. In this way, we will be able to perform further operations at the following points.

- David's diagram:

- Andres's diagram:

NETWORK CONFIGURATION

Based on the diagram created, we will assign the characteristics that are given to us, such as names, IP's, DNS, and more configurations. Afterward, we will verify that the configuration is correct when we send a message with the corresponding tool, and it gives us a positive result.

SERVICE CONFIGURATION

With the servers and devices already configured, we can move parameters within the services that each one has enabled. So, that we can check the functionality and data transmission between the different machines using application layer protocols, supported by those of the transport layer.

- **DNS**

We configured the requested DNS server with the properties and parameters that are in the guide, and then we tested them using the software's internal terminal, thus confirming that the connection is correct after starting the service.

- **MAIL**

On the mail servers, we will configure the 3 faculties of the diagram with the settings set in the guide. Then, we will start the service to perform a couple of actions.

Now we entered the emails and send a test message. If successful, we will respond and verify that the system is fully configured.

Mail Server: 27.200.0.52
Send Success.

- **FTP**

For this protocol, we need to set up a user on a server with HTTP running, so that we can connect and perform the requested actions.

For the following, the *telnet* command was used but since it is not open from the switch on port 23 it does not allow the connection and download of files, added to this when using Telnet we would not be allowed to download files but only have remote access.

```
C:\>telnet 27.100.0.32
Trying 27.100.0.32 ...
% Connection refused by remote host
C:\>
C:\>telnet 27.100.0.32
Trying 27.100.0.32 ...
% Connection refused by remote host
C:\>
```

Then, we enter the credentials to obtain access to download the machine using the *'ftp'* command, which will allow us to perform remote access.

```
* Connection refused by remote host
C:\>ftp www.sistemas.com
Trying to connect...www.sistemas.com
Connected to www.sistemas.com
220- Welcome to FT Ftp server
Username:David
331- Username ok, need password
Password:
230- Logged in
(passive mode On)
ftp>
```

Now that we have access to the server, we are going to download the files we need, in this case a plain text file as an example. Also, we are going to enter the device tab and verify that it now has the files we downloaded through the protocol.

IN THE REAL NETWORK

With the experience gained in the simulator, we will apply the same concepts and practices in real environments and working with real hardware and networks.

WIRESHARK

In this first part, we will use Wireshark to analyze how the application layer interacts with the transport layer through its ports. In this part, we will see how packets behave by analyzing each type found with queries.

First, we are going to query the page that was given to us where some protocols of the target layers are shown. To do this, we place the filter `http.host == "URL" && (tcp || dns || udp || http || tls || dns || ftp || ssh || telnet || smtp || pop || ntp || dhcp || smb)`, which aims to capture the packets coming from the page on different ports.

http.host=="laboratorio.js.esuelaing.edu.co" tcp

Next, we are asked to query the packets coming from DHCP and the ports of the target layers. To do this, we perform the following query `dhcp || bootp || udp.port == 67 || udp.port == 68`, which mainly filters the known ports for connection to the network, all after requesting that the DHCP

protocol be running again with the command `ipconfig /release ipconfig /renew`, after that, some packages will appear. There are some types:

- Discover request to obtain IP.
- Offer response from the DHCP server.
- Request: confirmation from the client.
- ACK final confirmation from the server.

The image shows a Wireshark packet capture of a DHCP process. The packet list on the left shows several DHCP messages. The packet details pane on the right shows the structure of a DHCP Discover packet (Transaction ID 0x565a). The packet bytes pane at the bottom shows the raw data of the packet. Overlaid on the Wireshark window are two network configuration windows. The first window, titled 'Ethernet adapter VMware Network Adapter VMnet1:', shows the following configuration: Connection-specific DNS Suffix: ., Link-local IPv6 Address: fe80::c8bc:feb8:6566:3cda%12, IPv4 Address: 192.168.172.1, Subnet Mask: 255.255.255.0, and Default Gateway: . The second window, titled 'Ethernet adapter Ethernet 6:', shows: Connection-specific DNS Suffix: ., Link-local IPv6 Address: fe80::1bca:2281:bdeb:166%23, IPv4 Address: 192.168.172.1, Subnet Mask: 255.255.255.0, and Default Gateway: . A third window, titled 'Ethernet adapter Bluetooth Network Connection:', shows Media State: Media disconnected and Connection-specific DNS Suffix: .

Finally, we are going to activate the Telnet protocol in order to capture the DHCP traffic. In our case, we enter the following part of the operating system; control panel>programs>Windows features. In this section, we have to activate the “Telnet Client” package, after which we can continue with the exercise.

Using filters, we will place the following query `tcp.port == 80 || tcp.port == 23`, which will allow us to obtain Telnet and HTTP packets. This will allow us to make HTTP and TELNET requests.

DNS SERVICE TEST

In this part, we have to do a test to examine and understand how DNS works in very specific cases. To do this, we perform a very specific test with the following 4 domains:

- **Escuelaing.edu.co:**
 - **Number of servers:** only 2 server: *ns1.escuelaing.edu.co* y *ns2.escuelaing.edu.co*.
 - **Life time:** since 02/05/1998 (+26 years).
 - **Person who registers the domain:** cointernet.
 - **Registration entity's ID:** 111111.
 - **Last update:** 06/10/2022 (+2 years).
 - **Record valid until:** 31/12/2025 (10 months remaining).
 - **Assigned IP range and by which registration authority:** 45.239.88.0/22 by LACNIC.
 - **Assigned company:** Escuela Colombiana de Ingeniería Julio Garavito.

NTP SERVER

When there are millions of machines in the world, it is important that they are somehow synchronized for certain tasks. In this case, global servers running the NTP protocol are used so that all machines that connect to that server can synchronize their clocks.

In this part, we are asked to set up a server and clients, using the protocol and virtual machines we already had. To do this, we start by installing NTP on Slackware with ``slackpkg install ntp`` and NetBSD with ``pkgin install ntp``. In the case of Windows, it has default access to the protocol through the console.

Now we are going to load the necessary configurations so that the system can start correctly. These configurations are simply to be able to connect to a root server with NTP and connect the other machines that will use the service that we are going to start.

Slackware:

The screenshot shows a terminal window titled '~: nano — Konsole'. The nano text editor is open, editing the file `/etc/ntp.conf`. The editor's status bar at the top indicates 'GNU nano 6.0' and 'Modified'. The menu bar includes 'File', 'Edit', 'View', 'Bookmarks', 'Plugins', 'Settings', and 'Help'. The toolbar shows 'New Tab', 'Split View', 'Copy', 'Paste', and 'Find'. The configuration file content is as follows:

```
server 0.pool.ntp.org iburst
server 1.pool.ntp.org iburst
server 2.pool.ntp.org iburst

# Permitir que los clientes locales se sincronicen con este servidor
restrict default kod nomodify notrap nopeer noquery
restrict 127.0.0.1
restrict ::1
restrict 192.168.1.0 mask 255.255.255.0 nomodify notrap

# Declarar este equipo como servidor
driftfile /var/lib/ntp/drift
logfile /var/log/ntp.log
```

The bottom of the terminal shows a status bar with keyboard shortcuts: `^G Help`, `^X Exit`, `^O Write Out`, `^R Read File`, `^W Where Is`, `^N Replace`, `^K Cut`, `^U Paste`, `^T Execute`, `^J Justify`, `^C Location`, and `^_ Go To Line`. The system tray at the bottom right displays the time '1:50 PM' and the date '3/6/25'.

NetBSD:

```
server 0.pool.ntp.org iburst
server 1.pool.ntp.org iburst
server 2.pool.ntp.org iburst

restrict default kod nomodify notrap nopeer noquery
restrict 127.0.0.1
restrict ::1
restrict 192.168.1.0 mask 255.255.255.0 nomodify notrap

driftfile /var/lib/ntp/drift
logfile /var/log/ntp.log

# $NetBSD: ntp.conf,v 1.28.16.1 2020/10/08 16:53:57 martin Exp $
#
#
# NetBSD default Network Time Protocol (NTP) configuration file for ntpd

"/etc/ntp.conf" 156L, 5617B written          10,1          Top
```

Finally, we are going to start the service using commands for each operating system.

- Slackware: ``chmod +x /etc/rc.d/rc.ntpd` y `/etc/rc.d/rc.ntpd start`.`
- NetBSD: ``echo ntpd=YES >> /etc/rc.conf` y `service ntpd start`.`
- Windows Server: ``w32tm /config /manualpeerlist:"192.168.1.100" /syncfromflags:manual /update` y `w32tm /resync`.`

Once we have everything ready, we are going to divide this process into 2, since the guide asks us to simulate 2 work groups.

Team 1:

Initialize the server and set the IP in the client configurations. Then, we see that when executing the command `ntpq -p` in Slackware and the command `w32tm /query /status` on Windows, BSD will be shown as connected, indicating that it is well configured and functional.

```

STRUCTURED CABLING & CABLE CONSTRUCTION

Now that we know how the transport and application layers work, we are going to punch our own Ethernet cables to be able to experiment and see the behavior of the network using the hardware provided for this specific practice. So that we understand the types of connections and their usefulness for the physical layer and data transport.

PATCH CORD CONSTRUCTION

Following the teacher's explanation of the punching procedure, we were requested to do a straight punch and a cross punch. But first we have to understand what each one is for and how they work.

- The straight-through network cable does not change its direction. Both ends use the same wiring standard: T-568A or T-568B. Therefore, both ends of the straight-through cable have the same colored wire arrangement. Thus, Pin 1 on connector A goes to Pin 1 on connector B, Pin 2 to Pin 2, etc.
- A crossover cable, as the name suggests, crosses or changes direction from one end to the other. Unlike a straight-through cable, a crossover cable uses different wiring standards at each end: one is the T568A standard and the other is the T568B standard.

Generally, a crossover cable is used to connect two devices of the same type, such as a PC to a PC or a switch to another switch. On the other hand, a straight-through cable connects two different devices to each other, such as a PC and a switch.

Now we can start the process that begins by cutting the cable to the size we want, then we untangle the cables and arrange them to start organizing them according to each type of connection we will make, then we place the cover and the connector so that the cables are at their highest point. Finally, we use the crimping tool so that the connector is tight, and the cables make contact with the copper.

- Andrés:

- David's:

After each cable was done, we proceed to use a device that allows us to perform a test, so we can know if it is functional or if we need to punch the cable again. In our case, it worked the first time, the direct ones indicated pairs of illuminated bulbs and the crossed ones if they complied with the sequences set by the device.

This means that our cables are ready to be tested in practice, meaning they can be used to make network connections to any compatible device.

PATCH PANEL CRIMPING

With the faceplate that they gave us in the lab, we are going to check that our cables do work. In addition, we can try another way of crimping cables with a hammer crimping tool, since the plate did not have pre-installed cables. Following the same process as before, we were able to patch with the tool and the guide on the plate itself.

Now we are going to connect the board to two computers. Since these two are connected by the board and the cables, we can know if there is communication between the two devices by using the terminal and a ping to the IP of the other machine. Obviously, a static IP was set to be able to carry out this procedure.

As you can see in the next images, it was possible to ping between the two machines, which proves that the cables and the connections made were done perfectly. In addition, we had the endorsement of the teacher, who validated that we did the complete practice.

```
C:\Users\Redes>ping 10.2.77.25

Pinging 10.2.77.25 with 32 bytes of data:
Reply from 10.2.77.29: Destination host unreachable.
Reply from 10.2.77.29: Destination host unreachable.

Ping statistics for 10.2.77.25:
    Packets: Sent = 2, Received = 2, Lost = 0 (0% loss),
Control-C
^C
C:\Users\Redes>ping 10.2.77.27

Pinging 10.2.77.27 with 32 bytes of data:
Reply from 10.2.77.27: bytes=32 time<1ms TTL=128
Reply from 10.2.77.27: bytes=32 time=1ms TTL=128
Reply from 10.2.77.27: bytes=32 time=1ms TTL=128
Reply from 10.2.77.27: bytes=32 time=1ms TTL=128

Ping statistics for 10.2.77.27:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 0ms, Maximum = 1ms, Average = 0ms

KNOWLEDGE OF THE UNIVERSITY'S CABLING

In this last part, we had to go to building I to observe how the components were distributed and their structuring throughout the building in terms of network elements.

The objective of the visit is to learn about and analyze the two types of cabling in structures. When the cabling runs inside the structure and is not easily visible, it is known as vertical cabling. In the case of horizontal cabling, the cables can be seen, and the connections between the different devices that interact with the network can be appreciated.

In this building we will be able to see the vertical cabling, as it is an open building where at first glance you can see the organisation of cables throughout the building.

In this same structure, horizontal cabling elements can be found just like in building B. Elements such as routes, clusters, racks, etc.

CONCLUTIONS

In this lab, we successfully achieved the proposed objectives, exploring both application layer protocols and the physical network infrastructure. Through Cisco Packet Tracer, we configured and analyzed essential services such as DNS, HTTP, FTP, and email, ensuring their proper functionality through connectivity tests and packet analysis.

On the physical side, we applied the structured cabling standard by constructing and verifying network cables, performing patch panel crimping, and testing continuity with specialized tools. These activities helped us understand the importance of proper and organized installation to ensure an efficient and scalable network infrastructure.

Additionally, with Wireshark, we analyzed real network traffic, identifying communication between protocols and evaluating the behavior of services like DHCP and HTTP, strengthening our ability to diagnose and optimize networks. We also performed NTP tests to synchronize time across multiple systems, ensuring temporal consistency in the infrastructure.

In conclusion, this lab provided us with a comprehensive experience, covering both the logical configuration of services and the physical implementation of the network, reinforcing our understanding of the importance of a well-structured IT infrastructure. Through teamwork and the application of theoretical knowledge in a practical environment, we strengthened key skills for network management and administration in real-world scenarios.
